Summary

Sea Surface Height (SSH) variations measured by satellite altimeters are widely used to estimate Sea Surface Currents (SSC) in oceanographic operational or research applications. The geostrophic balance approximation, which relates the pressure gradient, the current velocity, and the Coriolis force, is commonly employed to estimate SSC from SSH. It is known that under some configurations, the centrifugal acceleration, disregarded in the geostrophic formulation, should be included to the balance, leading to the cyclogeostrophic balance approximation. In general, solving the cyclogeostrophic balance can not be done analytically and numerical methods are needed. However, (1) existing iterative approaches are known to diverge, and ad-hoc methods are used to avoid local discontinuities; (2) publicly available, well maintained implementations are missing.

To overcome these limitations, we propose the Python package `jaxparrow.jaxparrow` formulates the cyclogeostrophic balance as a variational problem and solve it using a collection of well known optimizers. Its implementation heavily relies on JAX, the Python library bringing together automatic differentiation and just-in-time compilation, and the growing ecosystem around it. `jaxparrow` can be used as a package for an easy integration to existing oceanographic pipelines, or as a standalone executable working directly with NetCDF files.

Statement of need

Sea Surface Currents (SSC) can be easily approximated from satellite altimetry observations of the Sea Surface Height (SSH) using the geostrophic balance. Geostrophy describes the balance between the pressure gradient force (indirectly observed via SSH), and the Coriolis force. Geostrophic currents satisfy this equilibrium:

$$f\left(\vec{k} \times \vec{u}_g\right) = -g\nabla\eta, \tag{1}$$

where f is the Coriolis parameter, $\vec{k}$ the vertical unit vector, $\vec{u}_g$ the geostrophic velocity, g the gravity, and η the SSH.

However, as discussed by Bakun (2006), Charney (1955),and Maximenko & Niiler (2006), geostrophy alone is not always sufficient to accurately estimate SSC, and an advective term should be considered. For example, it has been shown by Penven et al. (2014) that, in the highly energetic Mozambique Channel, the geostrophic velocity can produce errors in the order of 30%. In these conditions, the centrifugal acceleration and the inertial effects of oceanic dynamics are no longer neglectable. To account for those forces, the advective term $\vec{u} \cdot \nabla\vec{u}$

is added back to the balance. Considering a horizontal, stationary, and inviscid flow, the momentum equation linking SSC velocities $\vec{u}$ with SSH —through geostrophic velocities $\vec{u}_g$ from Equation 1— can be expressed as:

$$\vec{u}_c - \frac{\vec{k}}{f} \times (\vec{u}_c \cdot \nabla \vec{u}_c) = \vec{u}_g, \tag{2}$$

where $\vec{u}_c$ is the cyclogeostrophic velocity.

Ocean data and services providers, such as Copernicus Marine Environment Monitoring Service (Taburet et al., 2019), use geostrophic balance to estimate SSC from SSH. Cao et al. (2023) demonstrates that applying cyclogeostrophic corrections to the global ocean over a 25-years period results in significantly different estimates of SSC. Ocean products could therefore greatly benefit from a robust and open estimation method of cyclogeostrophic currents, which, to our knowledge, is not presently available.

Numerical resolution of the cyclogeostrophic inverse problem

Because of the advective term $\vec{u}_c \cdot \nabla \vec{u}_c$, Equation 2 is nonlinear, and solving it analytically is conceivable only in idealized scenarios, making numerical approaches essential. The current state-of-the-art method to solve the cyclogeostrophic equation is the iterative formulation introduced by Arnason et al. (1962) and Endlich (1961), which consists of reaching balance using the following iterative scheme:

$$\vec{u}_c^{(n+1)} = \vec{u}_g + \frac{\vec{k}}{f} \times \left(\vec{u}_c^{(n)} \cdot \nabla \vec{u}_c^{(n)} \right), \tag{3}$$

with $\vec{u}_c^{(0)} = \vec{u}_g$. This approach is known to diverge since Arnason et al. (1962), and in practice (Ioannou et al., 2019; Penven et al., 2014) the residual $res = |\vec{u}_c^{(n+1)} - \vec{u}_c^{(n)}|$ is used to control point by point the iteration process. The iterative procedure is usually stopped when the residual locally falls below 0.01 m/s or starts to increase.

To avoid the local divergence issue of the iterative process, and its ad-hoc control, we propose to formulate the cyclogeostrophy as the variational problem:

$$J(\vec{u}_c) = \left\| \vec{u}_c - \frac{\vec{k}}{f} \times (\vec{u}_c \cdot \nabla \vec{u}_c) - \vec{u}_g \right\|^2, \tag{4}$$

where $\|.\|$ is the discrete L^2 norm. `jaxparrow` implements this approach, leveraging JAX (Bradbury et al., 2021). Thanks to JAX automatic differentiation capabilities, ∇J is numerically available, and the cyclogeostrophic currents are estimated by minimizing Equation 4 using a gradient-based optimizer, with $\vec{u}_c^{(0)} = \vec{u}_g$ as initial guess.

Application to the Alboran sea

The Alboran sea is an energetic area of the Mediterranean sea. We demonstrate below the need to consider cyclogeostrophy in this region, and the benefit of the variational formulation implemented in `jaxparrow`. The data and results presented here can be found in the Alboran sea notebook hosted on GitHub.

We use SSH and SSC from the eNATL60 configuration (Brodeau et al., 2020; Uchida et al., 2022) of the state-of-the-art NEMO ocean circulation model (Madec et al., 2022) as reference data. Figure 1 shows SSH, SSC, and normalized relative vorticities in this region.

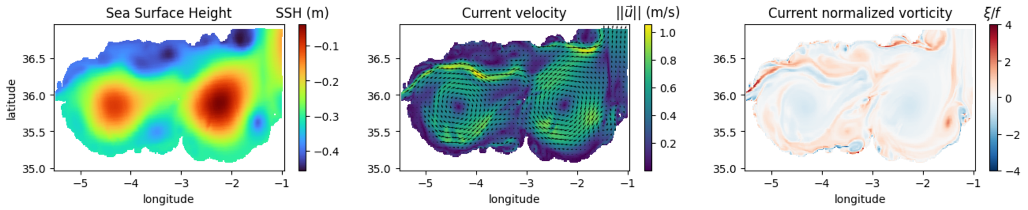

Figure 1: Reference data: on the left and middle panels, SSH and SSC velocity (colored by the magnitude, with arrows giving the direction) simulated by NEMO; on the right, the corresponding normalized vorticity.

Using SSH, jaxparrow can first estimate the geostrophic SSC with Equation 1. As geostrophy is a major mechanism governing ocean dynamics, vorticities derived from those velocities present an overall similarity with the ones obtain from NEMO data. However, we can clearly identify irregular areas (around (-4, 35.5), (-3, 36), and (-2.5, 35.5) in (longitude, latitude) coordinates, see Figure 2) where the geostrophic balance fails to accurately reconstruct SSC.

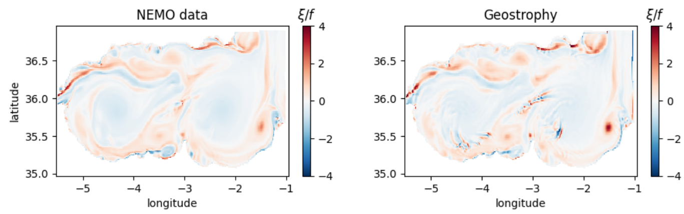

Figure 2: The qualitative comparison between reference (left panel) and geostrophic (right panel) normalized vorticities reveals several regions with highly erroneous estimations.

Starting from geostrophic currents, jaxparrow solves the variational formulation of the cyclogeostrophy (Equation 4), using in this example the classical gradient descent (Kantorovich & Akilov, 2016). As a result, almost all the problematic areas are now much more accurately reconstructed, leaving mainly costal or domain boundary regions with large differences from our reference vorticity (see Figure 3, left and middle panels). By evaluating the cyclogeostrophic disequilibrium (the functional J in Equation 4) along the optimization process, we observe that jaxparrow iteratively converges towards cyclogeostrophic balance (right panel of Figure 3).

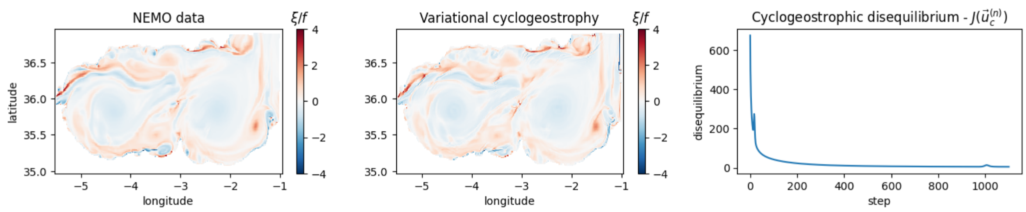

Figure 3: In contrast to the geostrophic approximation, variational cyclogeostrophy (middle panel) provide accurate reconstruction of the reference (left panel) normalized vorticities. The right panel demonstrates the fast convergence towards cyclogeostrophic balance.

For comparison, jaxparrow can also estimate the cyclogeostrophic currents using the iterative scheme (Equation 3). In this example, the evolution of J at each iteration reveals that this approach is not able to fill the cyclogeostrophic balance (see Figure 4, right panel). We even notice that this estimation is qualitatively worse than the geostrophy (left and middle panels of Figure 4).

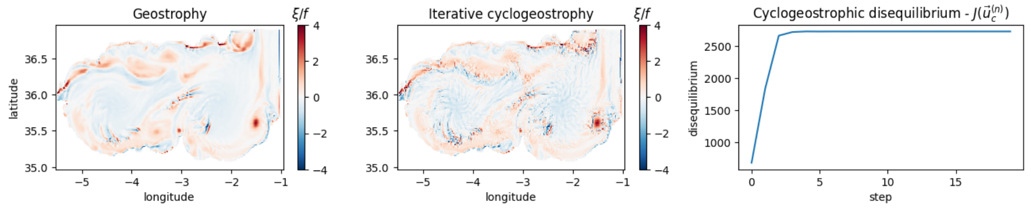

Figure 4: As exhibited in the right panel, the iterative approach diverges from the cyclogeostrophic balance; and we can notice from the two other panels that the resulting normalized vorticity is qualitatively worse than the geostrophic one.

Those qualitative observations are supported by more quantitative analysis. We computed the 1000 first percentiles of the vorticity distributions, and we observe, via a Q-Q plot (Wilk & Gnanadesikan, 1968), that the percentiles of the variational distribution are the closest to the ones of the reference distribution (Figure 5).

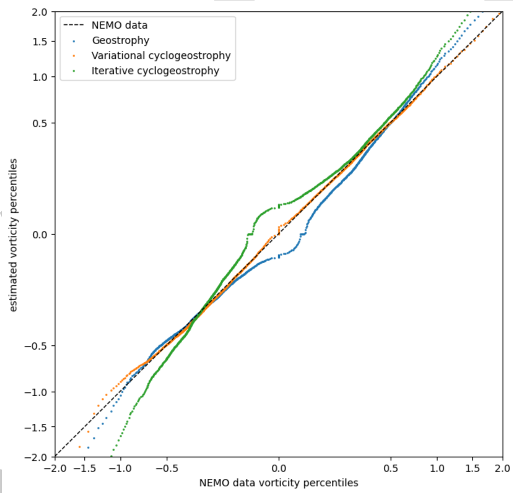

Figure 5: The percentiles of the normalized vorticity distributions demonstrate that our variational estimation of the cyclogeostrophy (in orange) corrects the geostrophy approximation (in blue), while the iterative scheme (in green) tends to diverge from the reference (in black).

Availability

Beside the novel variational formulation, `jaxparrow` also offers the first to our knowledge open implementation of the cyclogeostrophy inversion. The code is available on GitHub, with the specific tag `joss` for the version matching this publication; and the documentation, with pip-installation instructions, usage examples, and toy notebooks, is hosted on Read the Docs.
